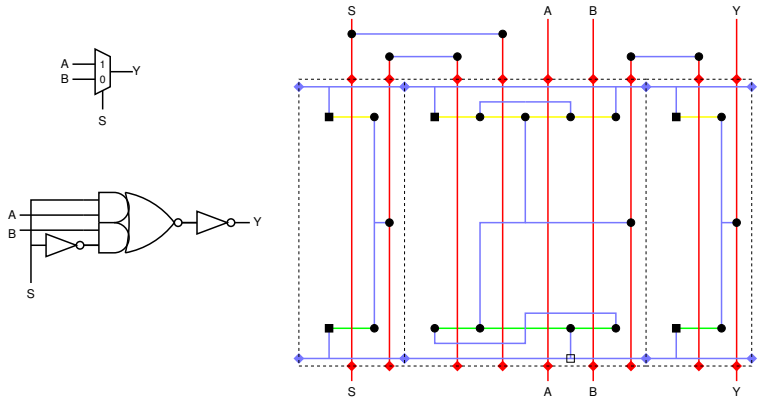
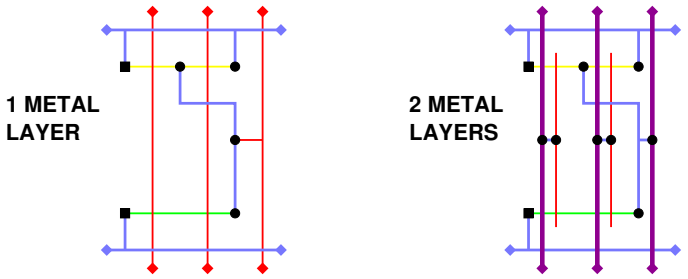
Multiple gates



Multiple gates

- Gates should all be of same height.
  - Power and ground rails will then line up when butted.
- All gate inputs and outputs are available at top and bottom.
  - All routing is external to cells.
  - Preserves the benefits of hierarchy.
- Interconnect is via *two conductor routing*.
  - In this case Polysilicon vertically and Metal horizontally.

Two-layer Metal



Most modern VLSI processes support two or more metal layers.
The norm is to use only metal for inter-cell routing.

usually Metal1 / Metal2 for horizontal / vertical inter-cell routing (and for power rails) (and for cell inputs and outputs).

Many ICs are designed using the standard cell method.

- Cell Library Creation

  A cell library, containing commonly used logic gates[1] is created for a process. This is often carried out by or on behalf of the foundry.

- ASIC[2] Design

  The ASIC designer must design a circuit using the logic gates available in the library.

  The ASIC designer usually has no access to the full layout of the standard cells and doesn't create any new cells for the library.

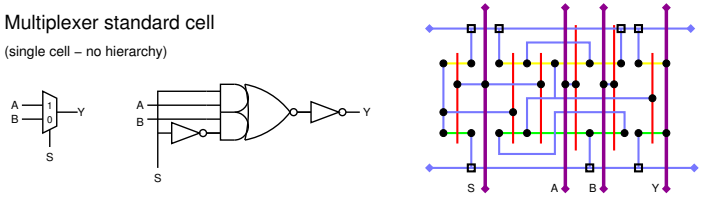
  Layout work performed by the ASIC designer is divided into two stages:

  - Placement
  - Routing

[1] note that a standard cell may include transistors from more than one basic function (e.g. NAND + inverter to give AND) but will normally be designed *flat* i.e. without layout hierarchy.
[2] Application Specific Integrated Circuit

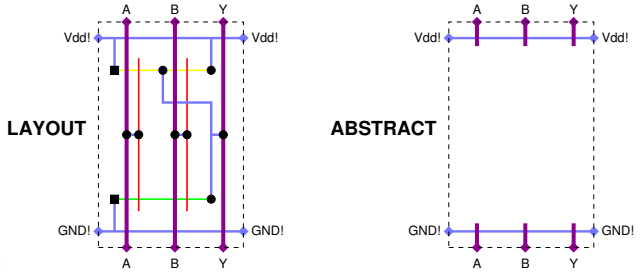
Choosing a set of cells for a cell library

- There is no set size for a cell library.
- Theoretically just one cell ( ) or one type of cell (, , , ...) is sufficient for a cell library.
- The use of more complex cells allows for designs optimised for area and/or performance:



- Which basic gates; which compound gates; which sequential gates?
- Do we provide different versions of the same gate (e.g. small area version, high drive version)? If so, how many different versions?

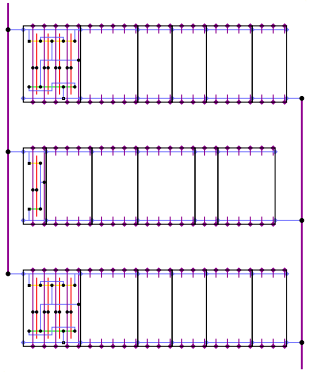
Layout and Abstract Views of a Standard Cell



The partial cell layout usually given to the ASIC designer is known as a black box or *abstract* view. The abstract:

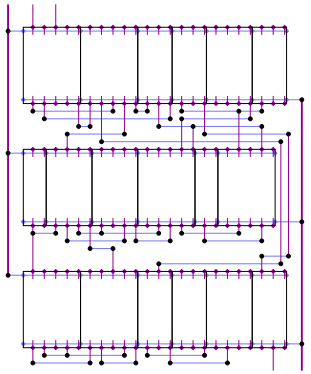
- must include cell ports and a cell boundary
- may include some or all of the metal mask information

Placement



Cells are placed in one or several equal length lines with inter-digitated power and ground rails.

Routing



In the routing channels between the cells we route metal1 horizontally and metal2 vertically.

Two conductor routing

- Conductor A / Conductor B for horizontal / vertical inter-cell routing [3]
- This logical approach means that we should never have to worry about signals crossing.

  This makes life considerably easier for a computer (or even a human) to complete the routing.
- We must only ensure that two signals will not meet in the same horizontal or vertical channel.
- Computer algorithms can be used to ensure placement of cells such that wires are short.[4]
- Further computer algorithms can be used to optimize the routing itself.

[3] In the two-metal example Conductor A is Metal1 and Conductor B is Metal2
[4] In VLSI circuits we often find that inter-cell wiring occupies more area than the cells themselves.

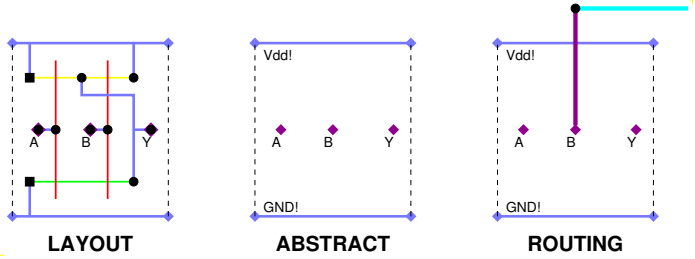
More Metal Layers

With three or more metal layers it is possible to take a different approach.
The simplest example uses three metal layers.

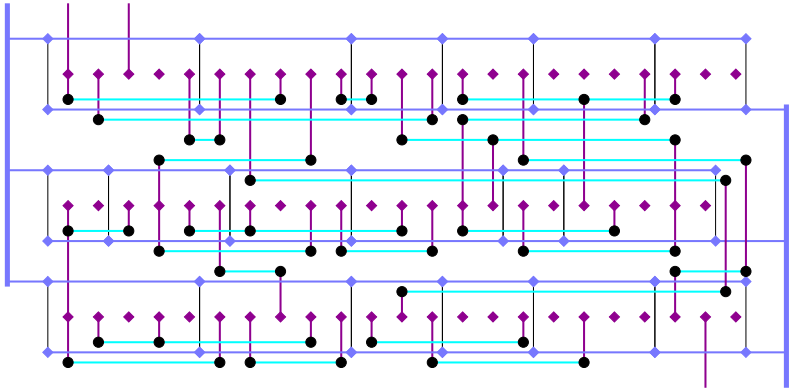
- Standard Cells

  Use only metal1 except for I/O which is in metal2
- Two Conductor Routing

  Uses metal2 and metal3

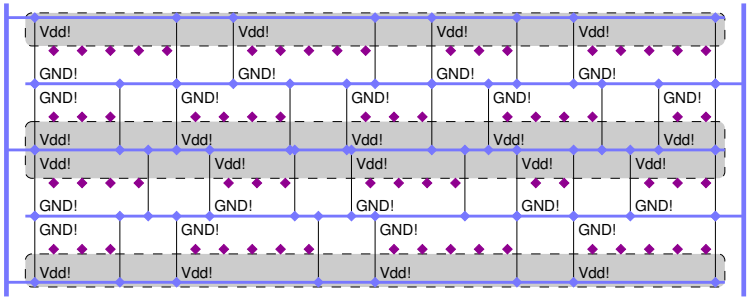


More Metal Layers



With this approach we can route safely over the cell to the specified pins leading to much smaller gaps between cell rows.

Alternative Placement Style



By flipping every second row it may be possible to eliminate gaps between rows.
N-wells are merged and power or ground rails are shared.
This approach is normally associated with sparse rows and non channel based routing algorithms.
