1947 First Transistor
John Bardeen, Walter Brattain, and William Shockley (Bell Labs)

1952 Integrated Circuits Proposed
Geoffrey Dummer (Royal Radar Establishment) - *prototype failed...*

1958 First Integrated Circuit
Jack Kilby (Texas Instruments) - *Co-inventor*

1959 First Planar Integrated Circuit
Robert Noyce (Fairchild) - *Co-inventor*

1961 First Commercial ICs
Simple logic functions from TI and Fairchild

1965 Moore's Law
Gordon Moore (Fairchild) observes the trends in integration.

Moore's Law

Predicts exponential growth in the number of components per chip.

1965 - 1975 Doubling Every Year

In 1965 Gordon Moore observed that the number of components per chip had doubled every year since 1959 and predicted that the trend would continue through to 1975.

Moore describes his initial growth predictions as "ridiculously precise".

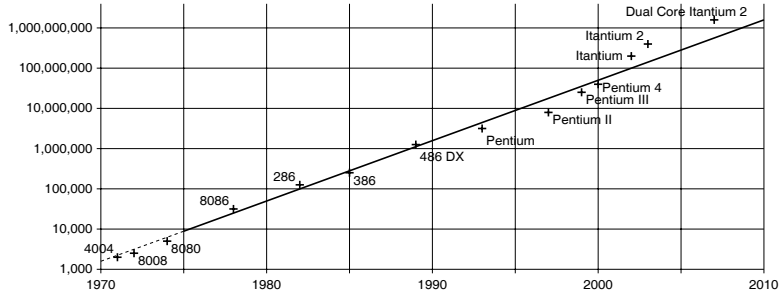
1975 - 2010 Doubling Every Two Years

In 1975 Moore revised growth predictions to doubling every two years.

Growth would now depend only on process improvements rather than on more efficient packing of components.

In 2000 he predicted that the growth would continue at the same rate for another 10-15 years before slowing due to physical limits.

Moore's Law at Intel[1]



[1]Intel was founded by Gordon Moore and Robert Noyce from Fairchild

Moore's Law; a Self-fulfilling Prophesy

The whole industry uses the Moore's Law curve to plan new fabrication facilities.

Slower - wasted investment

Must keep up with the Joneses[2].

Faster - too costly

Cost of capital equipment to build ICs doubles approximately every 4 years.

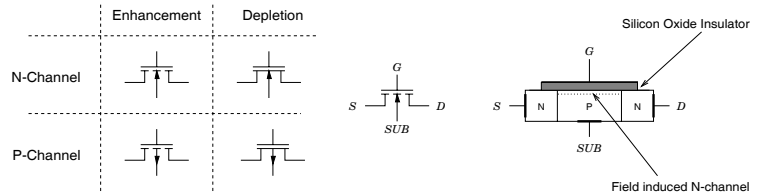
[2]or the Intels

Components for Logic

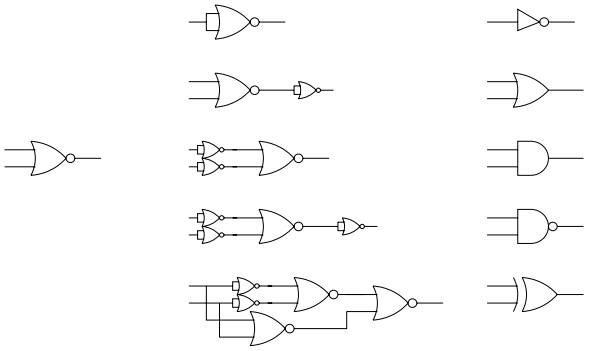
Diode

Bipolar Transistors

MOS Transistors

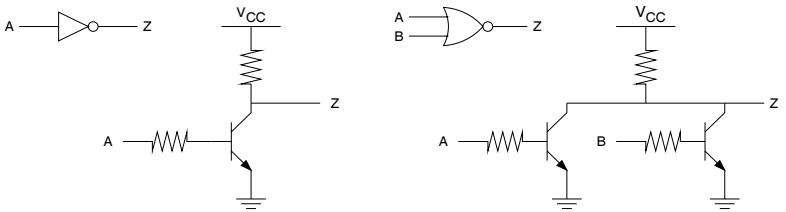


All functions can be realized with a single NOR base gate.[1]

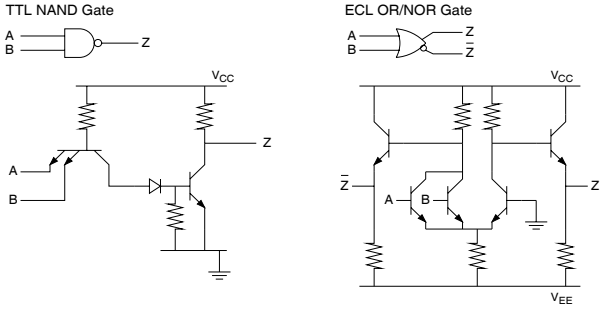


[1]NAND gates could be used instead.

RTL Inverter and NOR gate



Other Bipolar Technologies

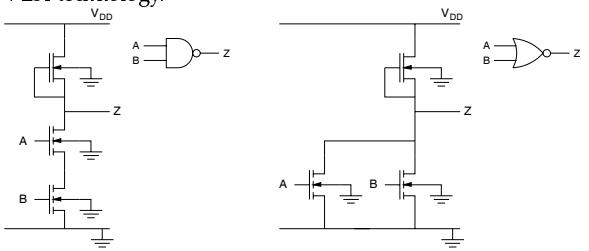


- **TTL** gives faster switching than RTL at the expense of greater complexity[2]. The characteristic multi-emitter transistor reduces the overall component count.
- **ECL** is a very high speed, high power, non-saturating technology.

[2]Most TTL families are more complex than the basic version shown here

Overview of Technologies

NMOS - a VLSI technology.

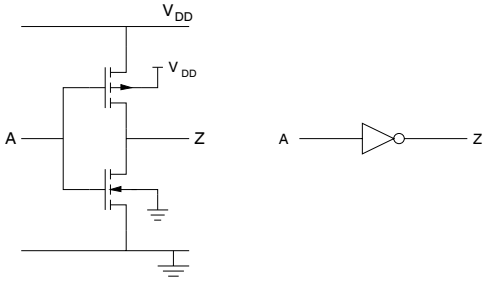


- Circuit function determined by series/parallel combination of devices.
- Depletion transistor acts as non-linear load resistor.
  Resistance increases as the enhancement device turns on, thus reducing power consumption.
- The low output voltage is determined by the size ratio of the devices.

Overview of Technologies

CMOS logic

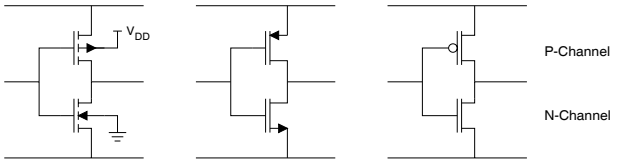
CMOS - *state of the art* VLSI.



- An active PMOS device complements the NMOS device giving:
  - rail to rail output swing.
  - negligible static power consumption.

Digital CMOS Circuits

Alternative representations for CMOS transistors

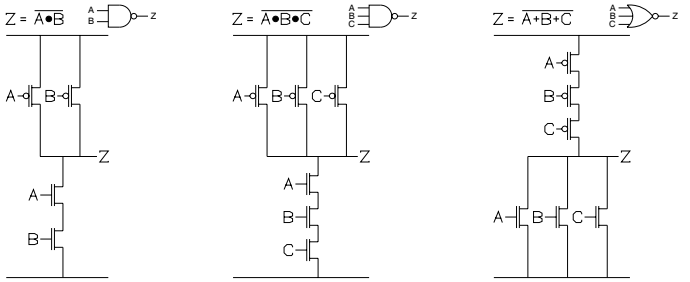


Various shorthands are used for simplifying CMOS circuit diagrams.

- In general substrate connections are not drawn where they connect to Vdd (PMOS) and Gnd (NMOS).
- All CMOS devices are enhancement mode.
- Transistors act as simple digitally controlled switches.

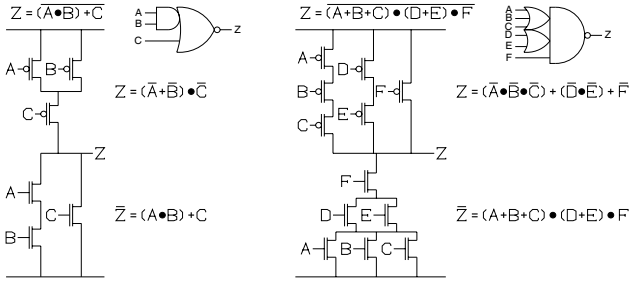
Digital CMOS Circuits

Static CMOS complementary gates



- For any set of inputs there will exist either a path to Vdd or a path to Gnd.

Compound Gates

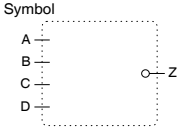


- All compound gates are inverting.
- Realisable functions are arbitrary AND/OR expressions with inverted output.

Compound Gate Example

$Z = \overline{(A \bullet B) + (C \bullet D)}$

Symbol



V_{DD}

Pull Up Network

$Z = f(\bar{A},\bar{B},\bar{C},\bar{D})$

$Z =$ .....

Z

Pull Down Network

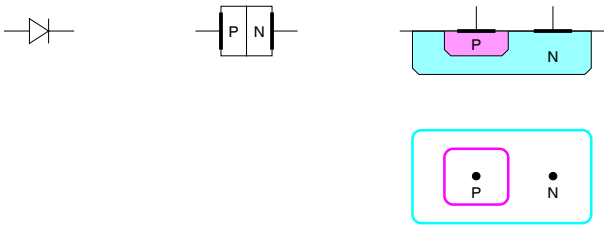
$\bar{Z} = f(A,B,C,D)$

$\bar{Z} = (A \bullet B) + (C \bullet D)$

GND

Diodes and Bipolar Transistors

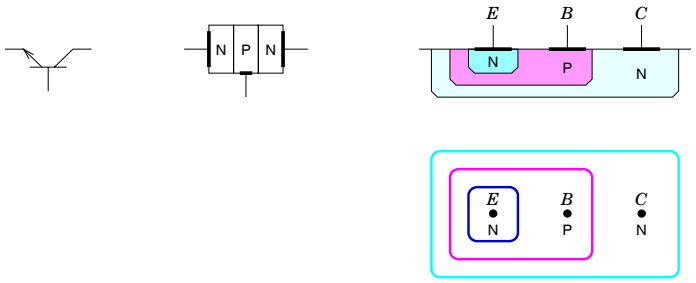
Diode



- Ideal structure - 1D
- Real structure - 3D
- Depth controlled implants.

Diodes and Bipolar Transistors

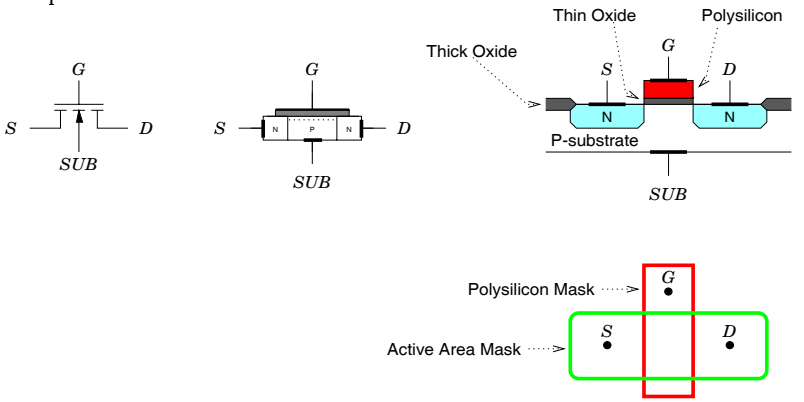
NPN Transistor



- Two n-type implants.

MOS Transistors

Simple NMOS Transistor

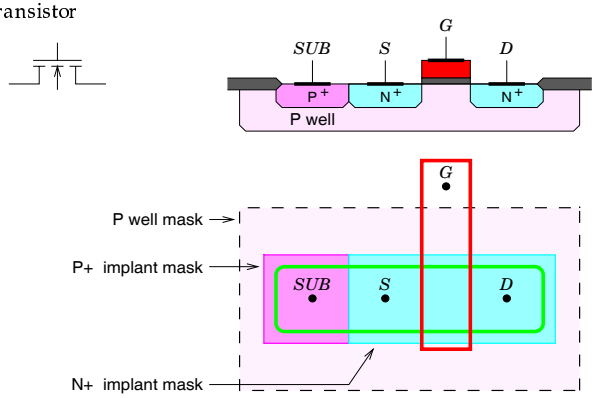


Simple NMOS Transistor

- Active Area mask defines extent of *Thick Oxide*.
- Polysilicon mask also controls extent of *Thin Oxide* (alias *Gate Oxide*).
- N-type implant has no extra mask.
  - It is blocked by thick oxide and by polysilicon.
  - The implant is *Self Aligned*.
- Substrate connection is to bottom of wafer.
  - All substrates to ground.
- Gate connection not above transistor area.
  - Design Rule.

MOS Transistors

NMOS Transistor

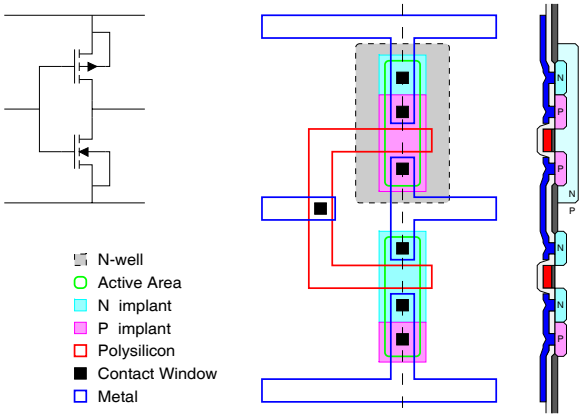


NMOS Transistor

Where it is not suitable for substrate connections to be shared, a more complex process is used.

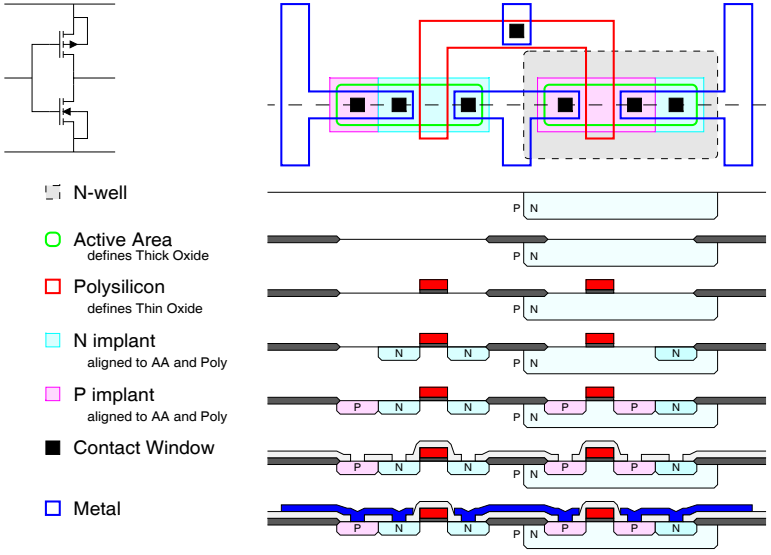
- Five masks must be used to define the transistor:
  - P Well
  - Active Area
  - Polysilicon
  - N+ implant
  - P+ implant
- P Well, for isolation.
- Top *substrate* connection.
- P+/N+ implants produce good *ohmic* contacts.

CMOS Inverter



CMOS Inverter

- The process described here is an *N Well process* since it has only an N Well.
  P Well and Twin Tub processes also exist.
- Note that the P-N junction between chip substrate and N Well will remain reverse biased.
  Thus the transistors remain isolated.
- N implant defines NMOS source/drain and PMOS substrate contact.
- P implant defines PMOS source/drain and NMOS substrate contact.



N-well
Active Area
defines Thick Oxide
Polysilicon
defines Thin Oxide
N implant
aligned to AA and Poly
P implant
aligned to AA and Poly
Contact Window
Metal

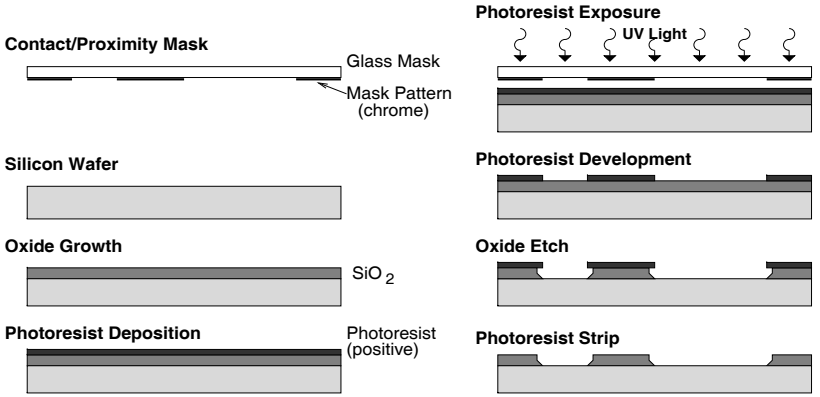
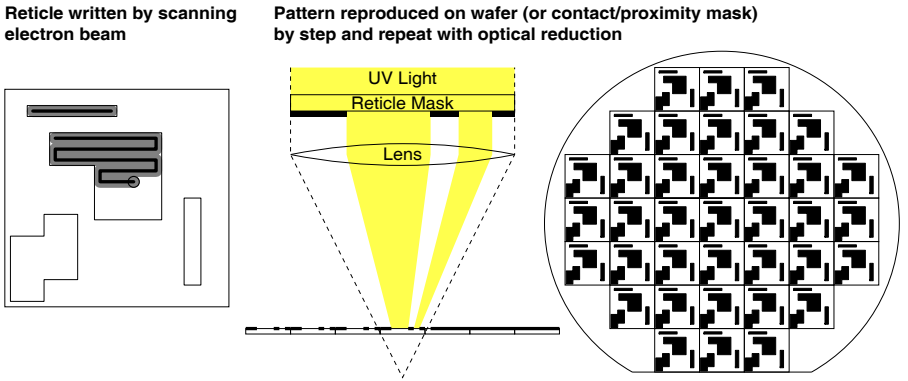
N

Photolithography



Mask Making

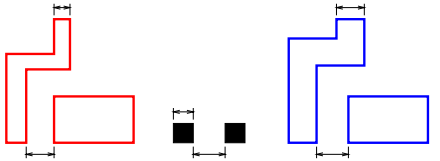


- Optical reduction allows narrower line widths.

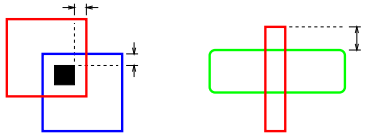
Design Rules

To prevent chip failure, designs must conform to design rules:

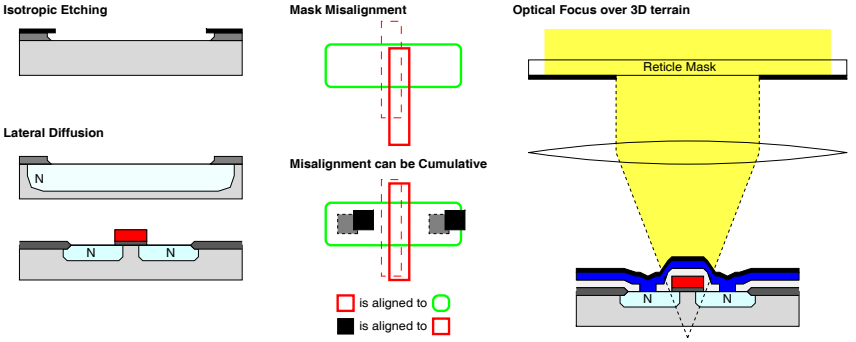
- Single layer rules



- Multi-layer rules

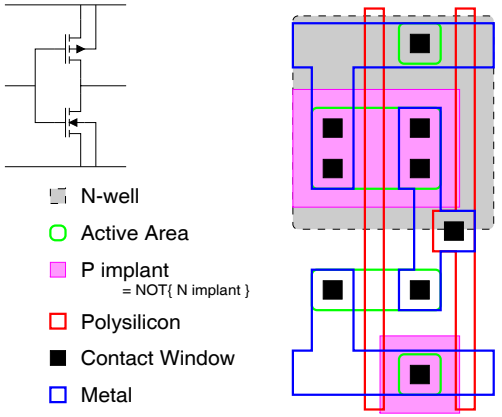


Derivation of Design Rules



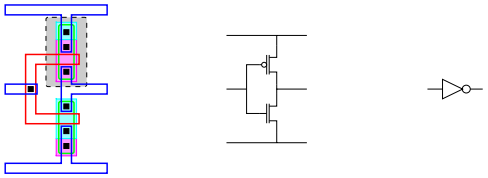
Design Rules

0.5 μm CMOS inverter



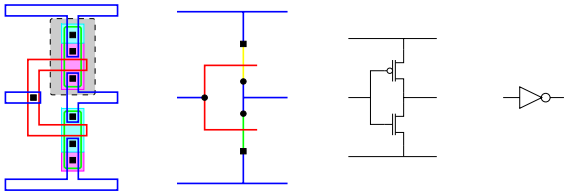
Abstraction

Levels of Abstraction



- Mask Level Design
  - Laborious Technology/Process dependent.
  - Design rules may change during a design!
- Transistor Level Design
  - Process independent, Technology dependent.
- Gate Level Design
  - Process/Technology independent.

Abstraction - Stick Diagrams



Stick diagrams give us many of the benefits of abstraction:

- Much easier/faster than full mask specification.
- Process independent (valid for any CMOS process).
- Easy to change.

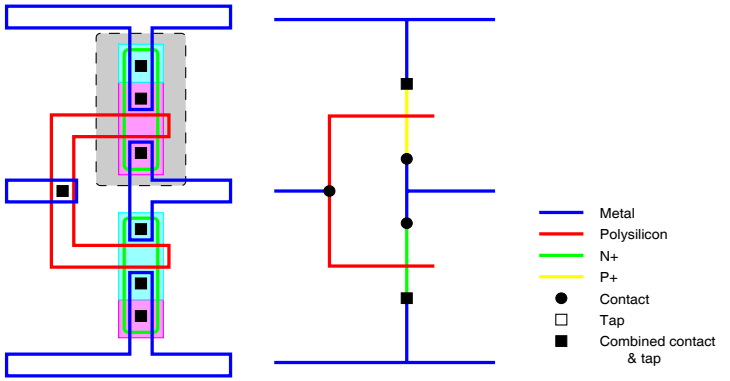
while avoiding some of the problems:

- Optimized layout may be generated much more easily from a stick diagram than from transistor or gate level designs.[1]

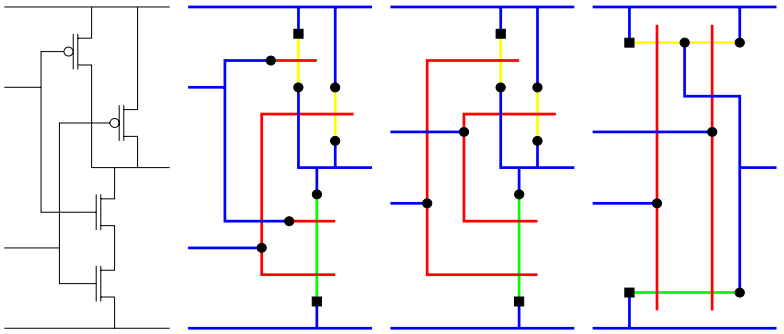
[1] note that all IC designs must end at the mask level.

Digital CMOS Design

Stick Diagrams

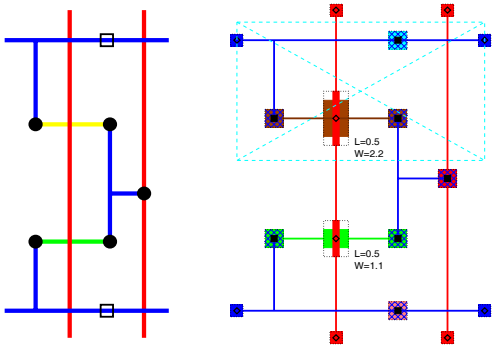


Stick Diagrams

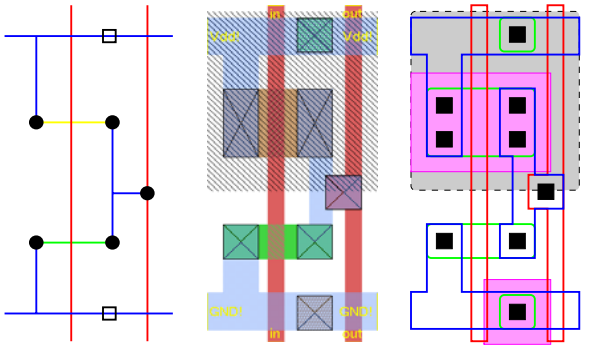


Stick Diagrams

- *Explore your Design Space*.
  - Implications of crossovers.
  - Number of contacts.
  - Arrangement of devices and connections.
- Process independent layout.
- Easy to expand to a full layout for a particular process.



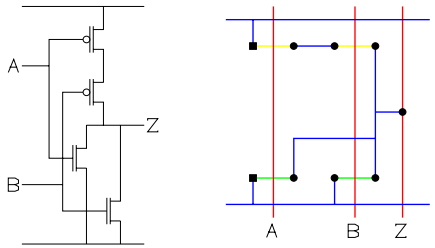
- Transistors are placed and explicitly sized.
  - components are joined with zero width wires.
  - contacts are automatically selected as required.
- A semi-automatic compaction process will create DRC correct layout.



- Log style design (sticks with width) - DRC errors are flagged immediately.
  - again contacts are automatically selected as required.
- On-line DRC leads to rapid generation of correct designs.
  - symbolic capture style compaction is available if desired.

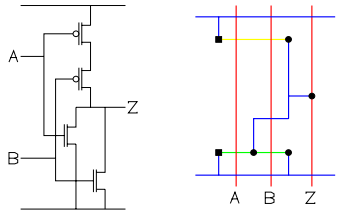
A logical approach to gate layout.

- *All complementary gates may be designed using a single row of n-transistors above or below a single row of p-transistors, aligned at common gate connections.*



Euler Path

- For the majority of these gates we can find an arrangement of transistors such that we can butt adjoining transistors.
  - Careful selection of transistor ordering.
  - Careful orientation of transistor source and drain.
- Referred to as *line of diffusion*.



Finding an Euler Path

Computer Algorithms

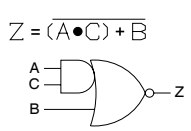
- It is relatively easy for a computer to consider all possible arrangements of transistors in search of a suitable Euler path.

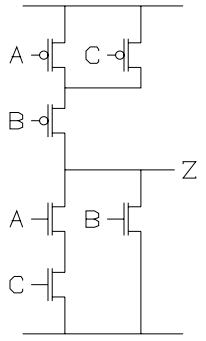
  This is not so easy for the human designer.

One Human Algorithm

- Find a path which passes through all n-transistors exactly once.
- Express the path in terms of the gate connections.
- Is it possible to follow a similarly labelled path through the p-transistors?
  - Yes – you've succeeded.
  - No – try again (you may like to try a p path first this time).

Finding an Euler Path



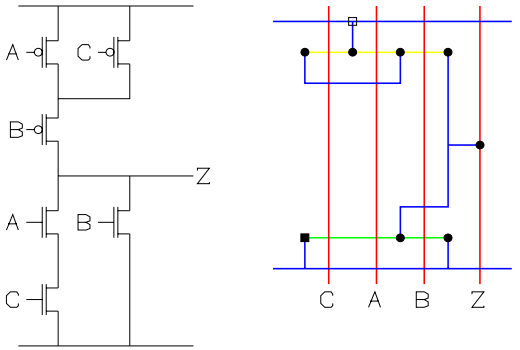


A–C–B
B–A–C
B–C–A
C–A–B ⇐

A–B–C
A–C–B
B–A–C
B–C–A
C–A–B ⇐
C–B–A

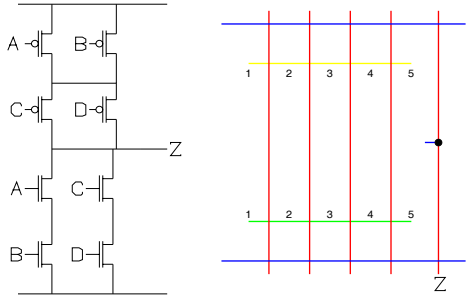
Here there are four possible Euler paths.

Finding an Euler Path



Euler Path Example

$Z = \overline{(A \bullet B) + (C \bullet D)}$



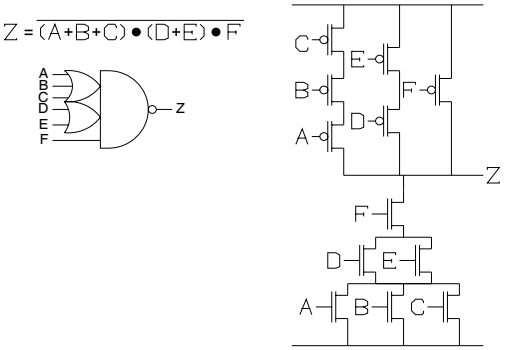
1. Find Euler path
2. Label poly columns
3. Route power nodes
4. Route output node
5. Route remaining nodes
6. Add taps[1] for PMOS and NMOS

A combined contact and tap, ■, may be used only where a power contact exists at the end of a line of diffusion. Where this is not the case a simple tap, ⊟, should be used.

[1] 1 tap is good for about 6 transistors – insufficient taps may leave a chip vulnerable to latch-up

Finding an Euler Path

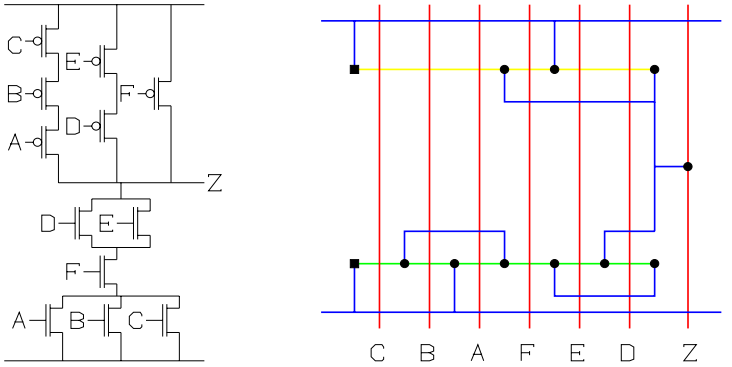
$Z = \overline{(A+B+C) \bullet (D+E) \bullet F}$



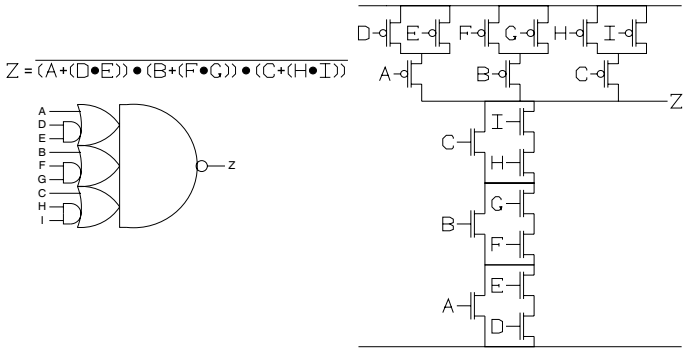
No possible path through n-transistors!

Finding an Euler Path

$Z = \overline{(A+B+C) \bullet (D+E) \bullet F}$

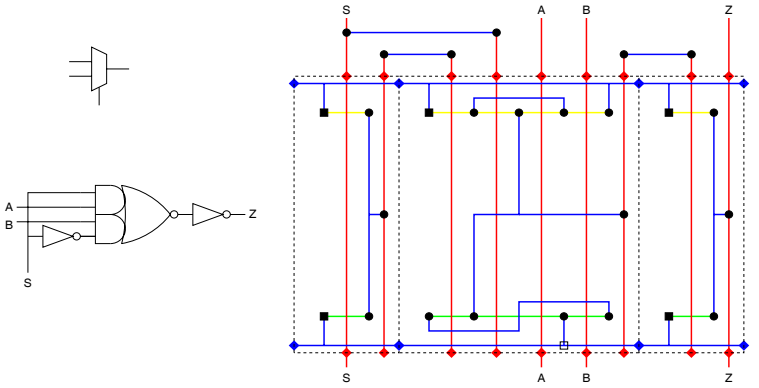


Finding an Euler Path



No possible path through p-transistors.
No re-arrangement will create a solution!

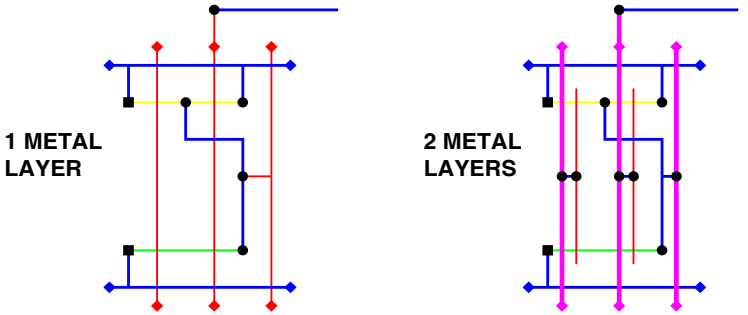
Multiple gates



Multiple gates

- Gates should all be of same height.
  - Power and ground rails will then line up when butted.
- All gate inputs and outputs are available at top and bottom.
  - All routing is external to cells.
  - Preserves the benefits of hierarchy.
- Interconnect is via *two conductor routing*.
  - In this case Polysilicon vertically and Metal horizontally.

Two-layer Metal



Most modern VLSI processes support two or more metal layers. The norm is to use only metal for inter-cell routing. Usually Metal1 horizontally (and for power rails) and Metal2 vertically (and for cell inputs and outputs).

Many ICs are designed using the standard cell method.

- Cell Library Creation

  A cell library, containing commonly used logic gates, is created for a process. This is often carried out by or on behalf of the foundry.

- ASIC[1] Design

  The ASIC designer must design a circuit using the logic gates available in the library.

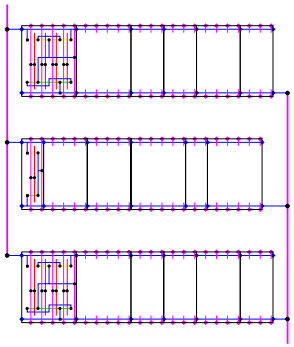
  The ASIC designer usually has no access to the full layout of the standard cells and doesn't create any new cells for the library.

  Layout work performed by the ASIC designer is divided into two stages:

  - Placement
  - Routing

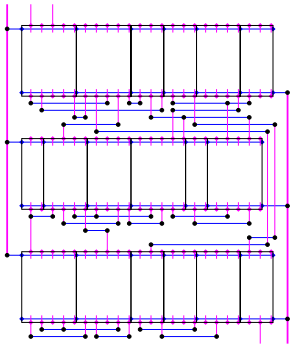
[1] Application Specific Integrated Circuit

Placement



Cells are placed in one or several equal length lines with inter-digitated power and ground rails.

Routing



In the routing channels between the cells we route metal1 horizontally and metal2 vertically.

Two conductor routing

- This logical approach means that we should never have to worry about signals crossing.

  This makes life considerably easier for a computer (or even a human) to complete the routing.
- We must only ensure that two signals will not meet in the same horizontal or vertical channel.
- Computer algorithms can be used to ensure placement of cells such that wires are short.[2]
- Further computer algorithms can be used to optimize the routing itself.

[2] In VLSI circuits we often find that inter-cell wiring occupies more area than the cells themselves.

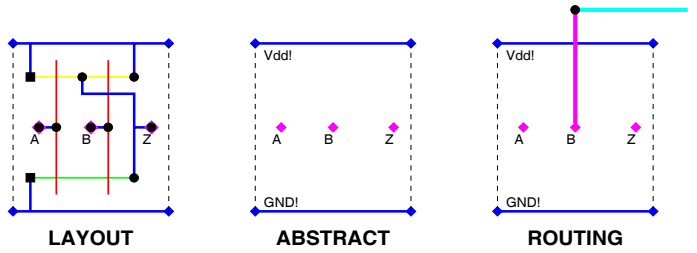
More Metal Layers

With three or more metal layers it is possible to take a different approach. The simplest example uses three metal layers.

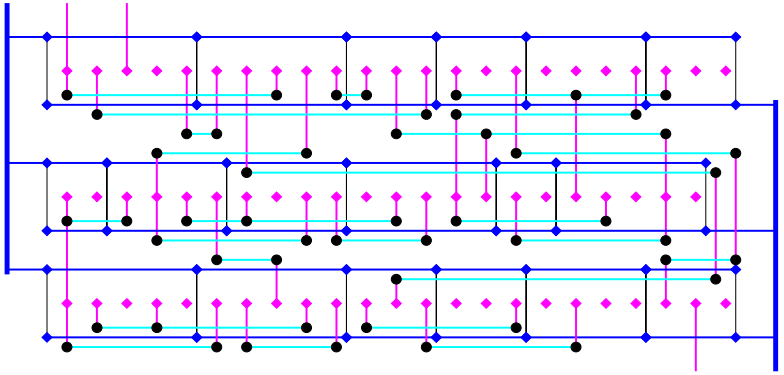
- Standard Cells

  Use only metal1 except for I/O which is in metal2
- Two Conductor Routing

  Uses metal2 and metal3

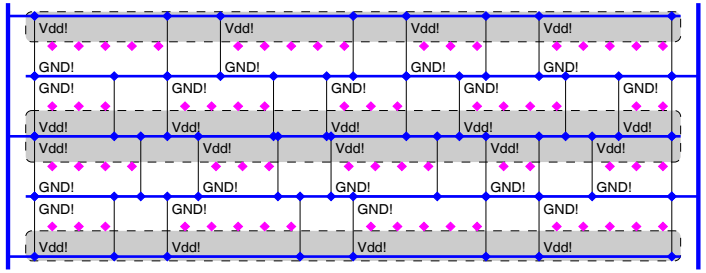


More Metal Layers



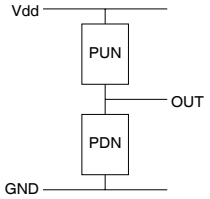
With this approach we can route safely over the cell to the specified pins leading to much smaller gaps between cell rows.

Alternative Placement Style



By flipping every second row it may be possible to eliminate gaps between rows.
N-wells are merged and power or ground rails are shared.
This approach is normally associated with sparse rows and non channel based routing algorithms.

Static CMOS Complementary Gates



- **Static**

  After the appropriate propagation delay the ouput becomes valid and remains valid.[1]

- **Complementary**

  For any set of inputs there will exist either a path to Vdd or a path to GND.

  Where this condition is not met we have either a high impedence output or a conflict in which the strongest path succeeds. Static CMOS **Non-complementary** gates make use of these possibilities.

[1] c.f. Dynamic logic which uses circuit capicitance to store state for a short time.

Pass Transistor Circuits

- Pass Transistor

  – Provides very compact circuits.

  – Good transmission of logic '0'.

  – Poor transmission of logic '1'.

    - - slow rise time
    - - degradation of logic value

The pass transistor is used in many dynamic CMOS circuits[2].

[2] where pull-up is performed by an alternative method

Pass Transistor Circuits

- Transmission Gate

  – For static circuits we would normally use a CMOS transmission gates:

    - - balanced *n* and *p* pass transistors
    - - faster pull-up
    - - slower pull-down

Pass Transistor Circuits

- Transmission Gate Layout

  – note that these circuits are not fully complementary[3] hence they do not immediately lend themselves to a *line of diffusion* implementation.

[3] since there are sets of inputs for which the output is neither pulled low nor high

Pass Transistor Circuits

- Transmission Gate Multiplexor

  - very few transistors 4 (+2 for inverter)
  - difficult layout may offset this advantage
    - - prime candidate for 2 level metal

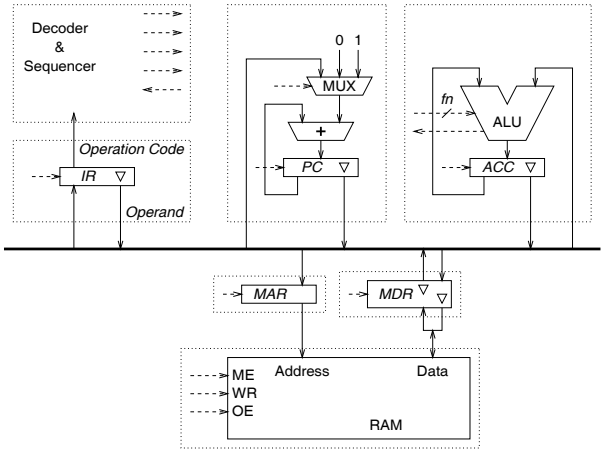
Pass Transistor Circuits

- Bus Wiring

  - distributed multiplexing[4]
  - only one inverter required per bank of transmission gates
  - greatly simplifies global wiring

[4] internal chip bus should never be allowed to float high impedance

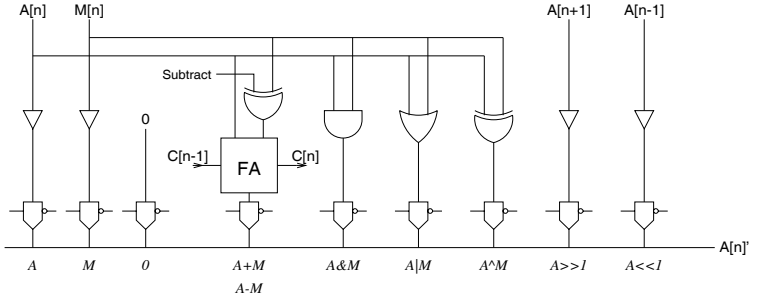
Bus Distributed Multiplexing



Ideal for signals with many drivers from different modules.

Bus Distributed Multiplexing

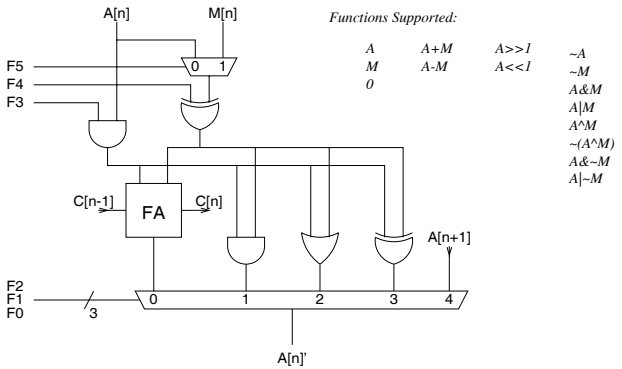
Implementation of bitslice ALU:[5]



- Separate circuit for each function
- Connected via distributed multiplexor

[5] Note that transmission gates have no drive capability in themselves. Here a good drive is ensured by providing buffers.

Bus Distributed Multiplexing



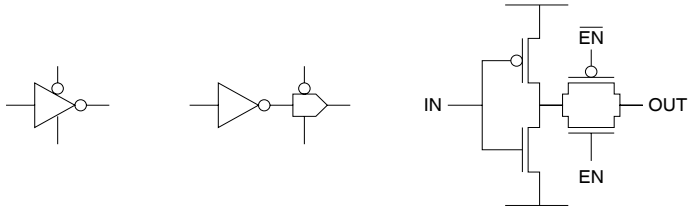
Functions Supported:

A	*A+M*	*A>>1*	*~A*
M	*A-M*	*A<<1*	*~M*
0			*A&M*
			A|M
			A^M
			~(A^M)
			A&~M
			A|~M

- Single optimized ALU module
- Multiplexing is not distributed
- Multiplexor implementation may use transmission gates

Pass Transistor Circuits

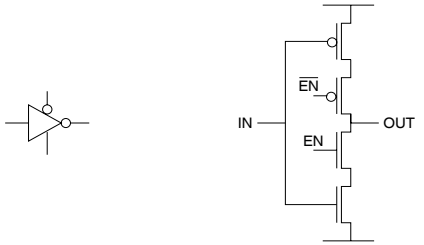
- Tristate Inverter



– Any gate may have a tri-state output by combining it with a transmission gate.

Pass Transistor Circuits

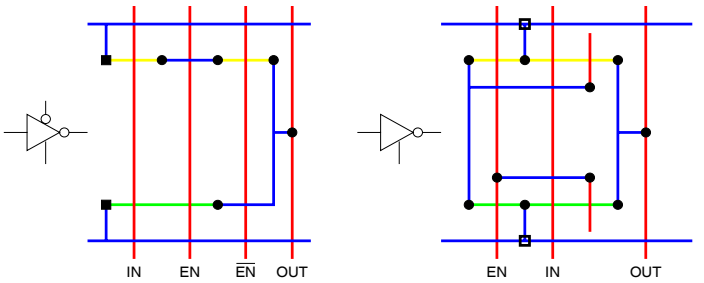
- Tristate Inverter



– Alternatively the transmission gate may be incorporated into the gate.
- - one connection is removed - easier to layout
- - also easier to simulate!

Pass Transistor Circuits

- Tristate Inverter Layout



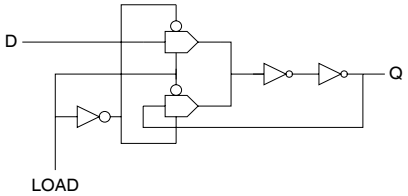
Pass Transistor Circuits

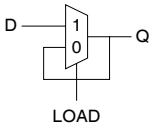
- Tristate Inverter Bus Driver

  - a tristate inverting buffer is often used to drive high capacitance bus signals
  - transistors may be sized as required

Latches and Flip-Flops

- CMOS transmission gate latch



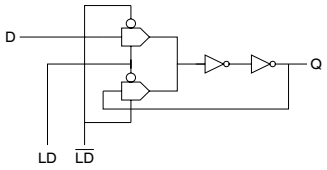


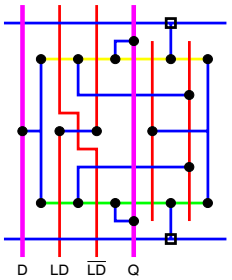
A simple transparent latch can be build around a transmission gate multiplexor

- transparent when load is high
- latched when load is low
- two inverters are required since the transmission gate cannot drive itself

Latches and Flip-Flops

- Transmission gate latch layout

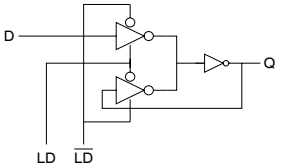


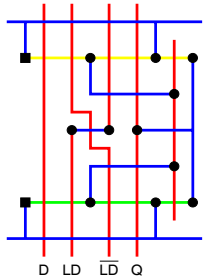


- a compact layout is possible using 2 layer metal

Latches and Flip-Flops

- A simpler layout may be achieved using tristate inverters.

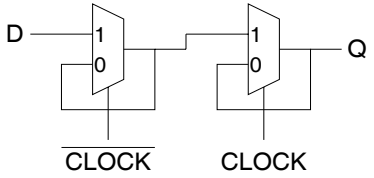




- this design requires two additional transistors but may well be more compact.

Latches and Flip-Flops

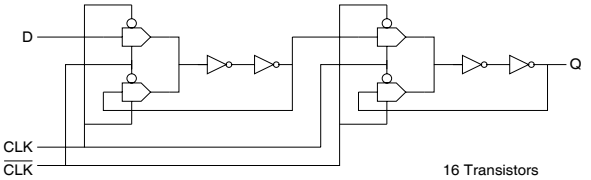
- For use in simple synchronous circuits we use a pair of latches in a master slave configuration.



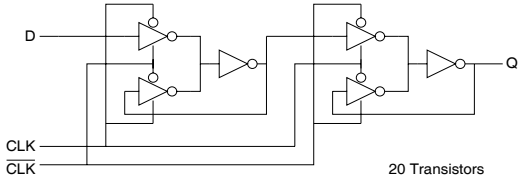
- this avoids the race condition in which a transparent latch drives a second transparent latch operating on the same clock phase.
- the circuit behaves as a rising edge triggered D type flip-flop.

Latches and Flip-Flops

- Transmission gate implementation

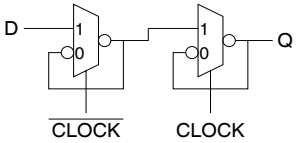


- Tristate inverter implementation

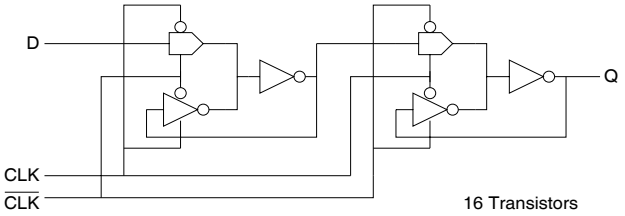


Latches and Flip-Flops

- Alternative configuration

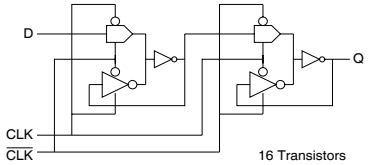


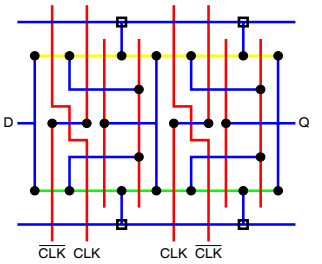
– Implementation



Latches and Flip-Flops

- Layout of master slave D type.

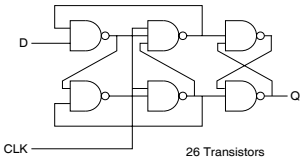


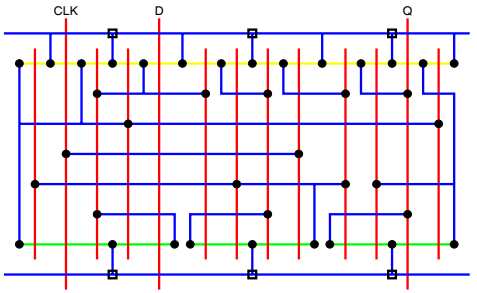


– very compact using alternative configuration.

Latches and Flip-Flops

- For the same functionality we could use an edge triggered D type:

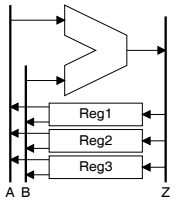


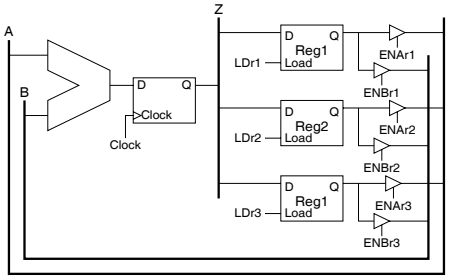


– a few more transistors
– more complex wiring
– simpler clock distribution

Register File

Where we have large amounts of storage the use of individual latches can lead to space saving.

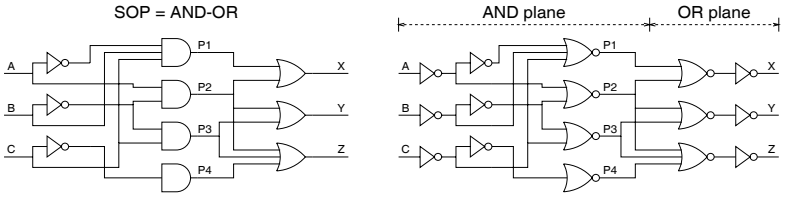




- Load signals must be glitch free with tightly controlled timing.
- Edge Triggered D-type prevents a race condition ($Reg1 \leftarrow Reg1 + Reg2$).

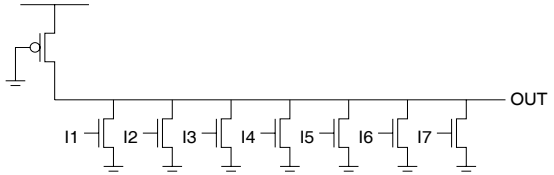
PLA structures

Programmable Logic Array structures provide a logical and compact method of implementing multiple SOP (Sum of Products) or POS expressions.



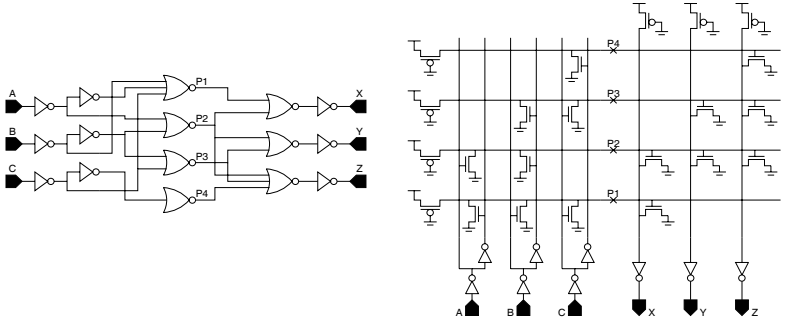
Most PLA structures employ pseudo-NMOS NOR gates using a P-channel device in place of the NMOS depletion load.

Pseudo-NMOS NOR gate



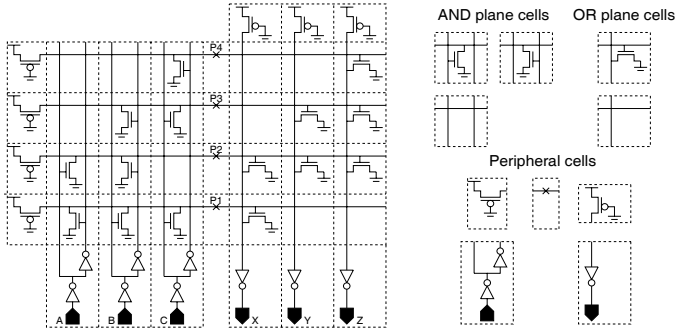
- Unlike complementary CMOS circuits, these gates will dissipate power under static conditions (since the P device is always on).
- The P and N channel devices must be ratioed in order to create the required low output voltage.
- This ratioing results in a slower gate, although there is a trade-off between gate speed and static power dissipation.

PLA structure



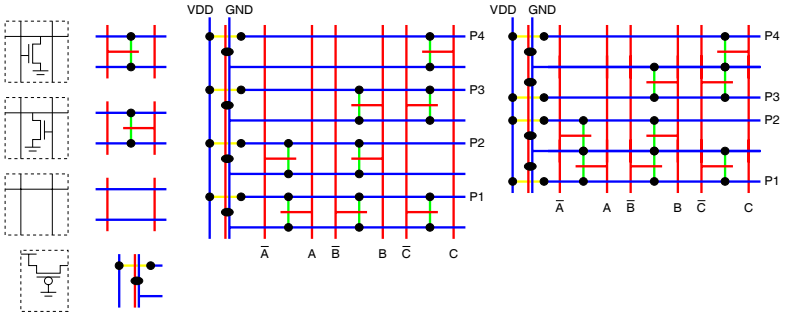
- A regular layout is employed, with columns for inputs and outputs and rows for intermediate expressions.

PLA structure



- Layout is simply a matter of selecting and placing rectangular cells from a limited set.

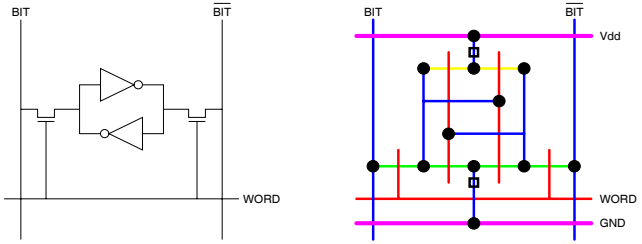
PLA structure



- Conversion to *sticks* is straight forward with opportunities for further optimization.

Static RAM

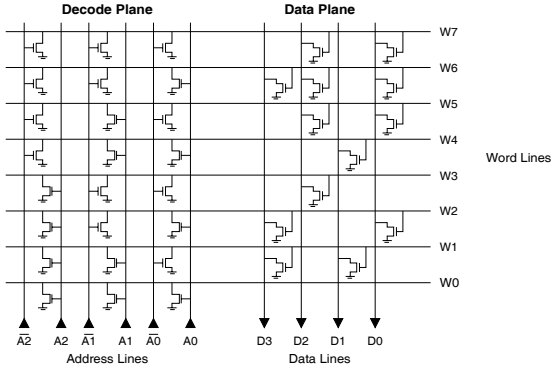
- Used for high density storage on a standard CMOS process.
- Short lived conflict during write - NMOS transistors offer stronger path.
- Differential amplifiers are used for speedy read.



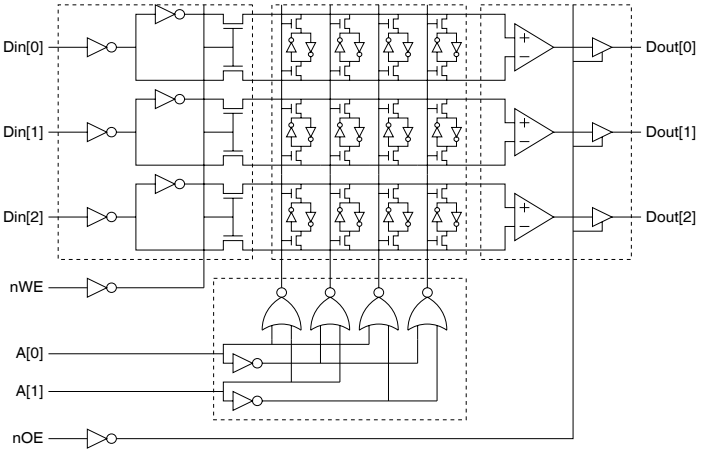
Standard 6 transistor static RAM cell.

ROMs

- A ROM may simply be a PLA with fixed decoder plane[1] and programmable data plane.



[1]RAM structures can make use of the same decode plane.



System Design Choices

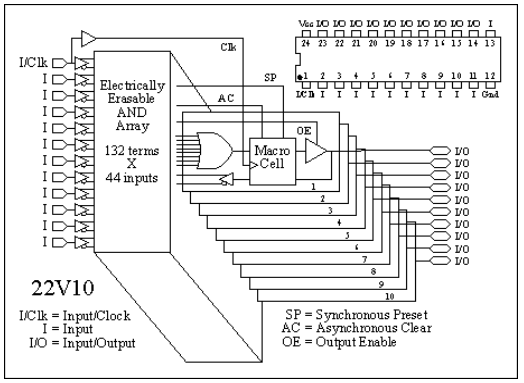
- Programmable Logic
  - PLD
    e.g. PAL 22V10, ICT PEEL22CV10, Lattice ispGAL22V10
  - Field Programmable Gate Array (FPGA)
    e.g. Xilinx XC4013, Altera Cyclone EP1C12
- Semi-Custom Design
  - Mask Programmable Gate Array
    e.g. ECS CMOS Gate Array
    Altera HardCopy II structured ASICs
  - Standard Cell Design
    e.g. Alcatel Mietec MTC45000 0.35μm cell library
- Full Custom Design

System Design Choices

- Programmable Logic START HERE
  - Best possible design turnaround time
  - Cheapest for prototyping
  - Best time to market
  - Minimum skill required
- Semi-Custom Design
- Full Custom Design
  - Cheapest for mass production
  - Fastest
  - Lowest Power
  - Highest Density[1]
  - Most skill required

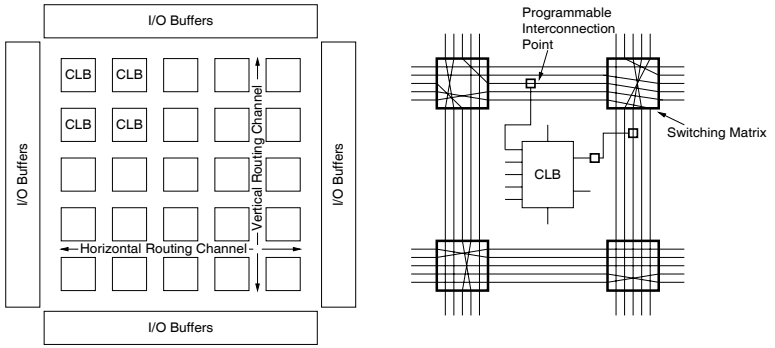
[1] optimization limited by speed/power/area trade off

Programmable Logic



- One time use - Fuse programmable.
- Reprogrammable - UV/Electrically Erasable.

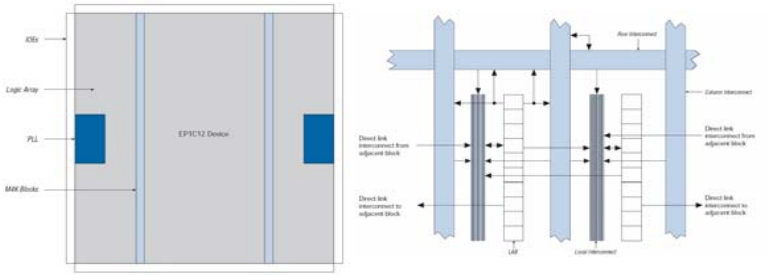
Field Programmable Gate Array – Xilinx XC4000



- Configurable Logic Blocks & I/O Blocks[2]
- Programmable Interconnect

[2] Xilinx XC4013 has 576 (24×24) CLBs and up to 192 (4×48) user I/O pins.

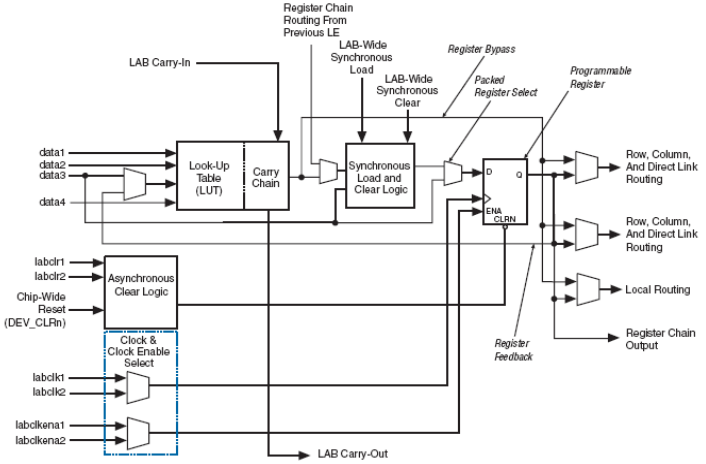
Field Programmable Gate Array – Altera Cyclone



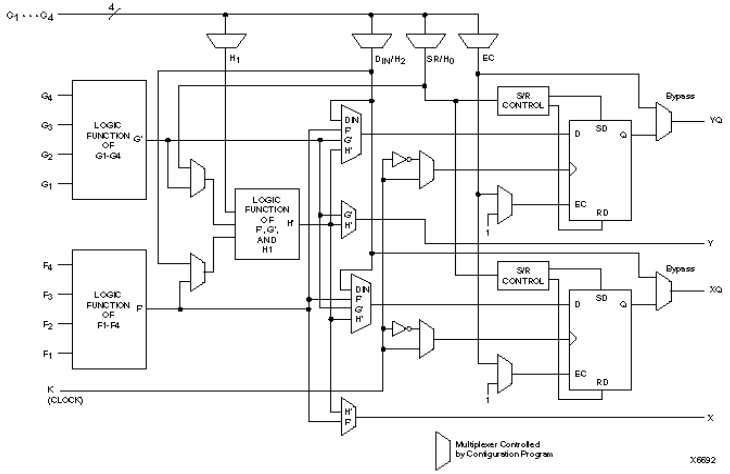
- Logic Array Blocks, M4K Ram Blocks & I/O Elements[3]
- Programmable Interconnect

[3] Altera Cyclone EP1C12 has 12060 Logic Elements (arranged as 1206 Logic Array Blocks) and and up to 249 user I/O pins.

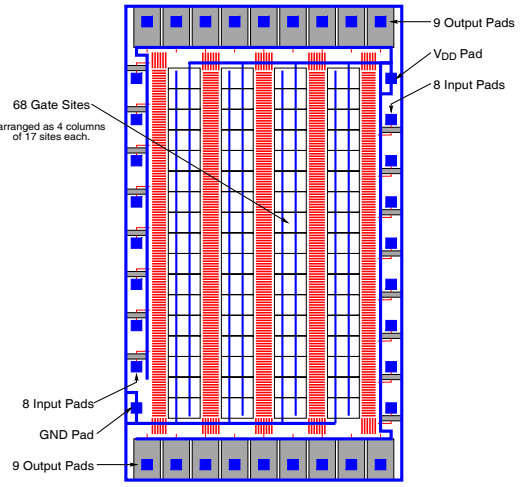
Field Programmable Gate Array – Altera Cyclone LE



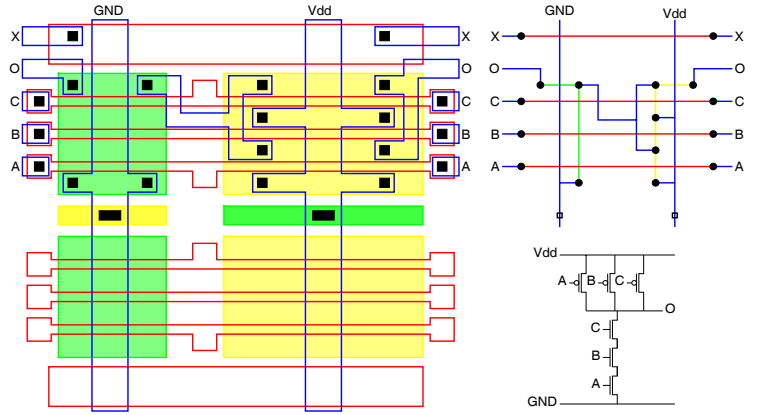
Field Programmable Gate Array – Xilinx XC4000 CLB



Mask Programmable Gate Array



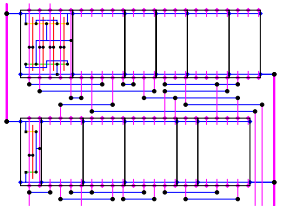
Mask Programmable Gate Array



- Customize Metal and Contact Window masks only.

Standard Cell Design

- Logic Functions



- Auto Generated Macro Blocks
  - PLA
  - ROM
  - RAM
- System Level Blocks
  - Microprocessor core[4]

[4]Will support System On Chip applications.

Full Custom

All design styles need full custom designers

- to design the base programmable logic chips
- to design building blocks for semi-custom

Where large ASICs use full custom techniques they are likely to be used alongside semi-custom techniques.

e.g. Hand-held computer game chip

- Full custom bitslice datapath
  hand crafted for optimum area efficiency and low power consumption
- Standard cell controller
- Macro block RAM, ROM
