#### A logical approach to gate layout.

• All complementary gates may be designed using a single row of n-transistors above or below a single row of p-transistors, aligned at common gate connections.

#### **Euler Path**

- For the majority of these gates we can find an arrangement of transistors such that we can butt adjoining transistors.
  - Careful selection of transistor ordering.
  - Careful orientation of transistor source and drain.
- Referred to as line of diffusion.

#### Finding an Euler Path

#### Computer Algorithms

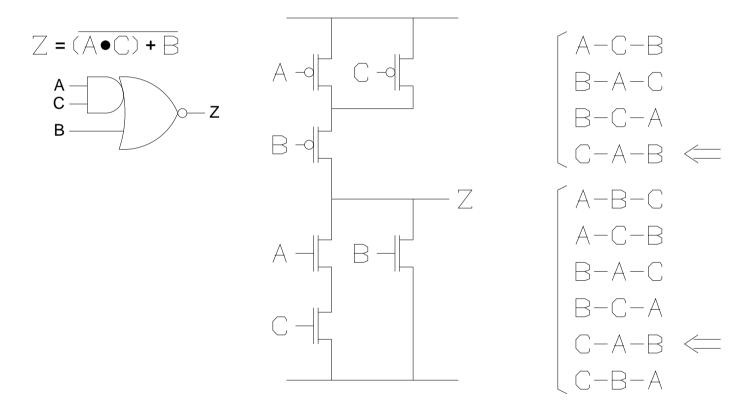

• It is relatively easy for a computer to consider all possible arrangements of transistors in search of a suitable Euler path.

This is not so easy for the human designer.

#### One Human Algorithm

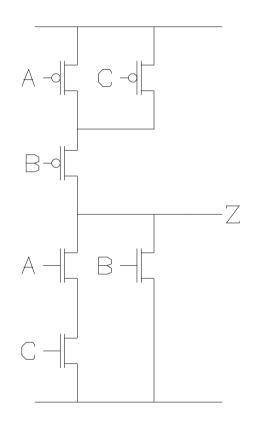

- Find a path which passes through all n-transistors exactly once.
- Express the path in terms of the gate connections.
- Is it possible to follow a similarly labelled path through the p-transistors?
  - Yes you've succeeded.
  - No try again (you may like to try a p path first this time).

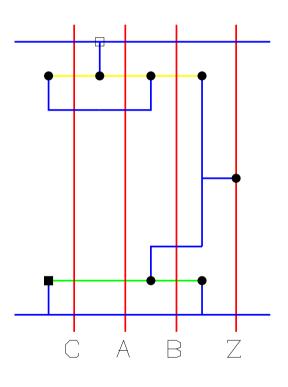

#### Finding an Euler Path

Here there are four possible Euler paths.

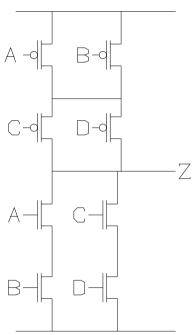

# Finding an Euler Path

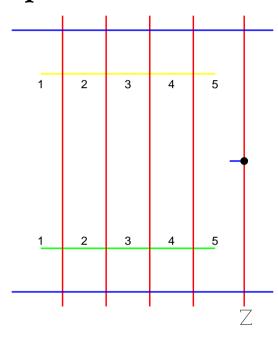

#### Euler Path Example

 $Z = (\overline{A \bullet B}) + (C \bullet D)$ 

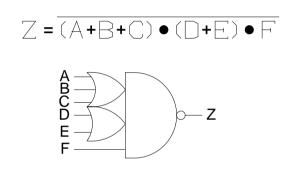

- 1. Find Euler path
- 3. Route power nodes
- 5. Route remaining nodes

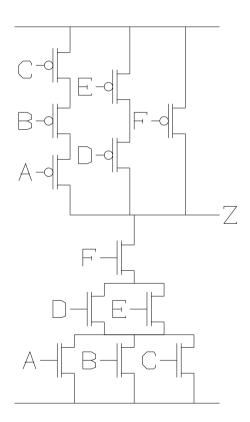

- 2. Label poly columns
- 4. Route output node
- 6. Add taps<sup>1</sup> for PMOS and NMOS

A combined contact and tap,  $\blacksquare$ , may be used only where a power contact exists at the end of a line of diffusion. Where this is not the case a simple tap,  $\blacksquare$ , should be used.

<sup>11</sup> tap is good for about 6 transistors – insufficient taps may leave a chip vulnerable to latch-up

## Finding an Euler Path

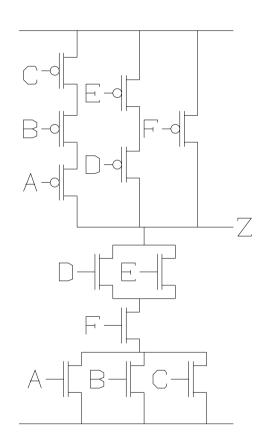

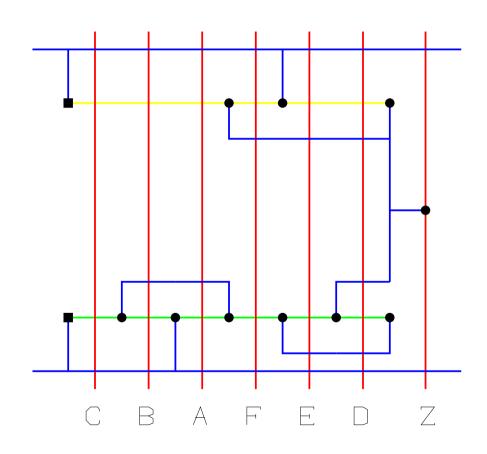

No possible path through n-transistors!

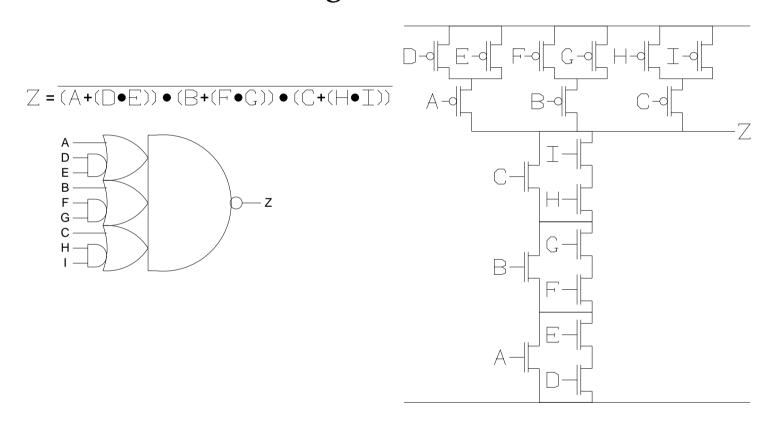

## Finding an Euler Path

## Finding an Euler Path

No possible path through p-transistors. No re-arrangement will create a solution!
